

An interactive pricing dashboard built on your parametric workbook.

Trigger Console

Live pricing exploration for the hurricane wind parametric — expected loss, volatility and return periods, recomputed from the event set below.

⬆ Upload event set (.xlsx / .csv)

Cat-in-Circle Trigger Zone

reference geometry for scoring site wind against a storm track

INNER CIRCLE RADIUS

75

miles

OUTER CIRCLE RADIUS

150

miles

The concentric-circle diagram with two editable radii, defaulted to 75mi inner / 150mi outer (matching the decay-length assumption). I want to flag one honesty point rather than fake it: this panel documents the spatial trigger rule (inner circle = full intensity, between the two = attenuated, beyond outer = no payout)

Track within the inner circle: score at full peak intensity. Between inner and outer: attenuate toward the site. Beyond the outer circle: no payout. This defines how a real track would be scored — the sample and uploaded data here already carry a resolved site wind speed, so this panel documents the rule rather than re-deriving the 49,999-row sample from it.

Wind-Speed Exceedance Probability

annual probability the site sees at least this wind speed, from the active sample

Read as a return period: a probability of 0.01 at a given wind speed is a 1-in-100-year threshold.

Payout Outcome Breakdown

share of simulated years landing in each trigger tier

<Cat1 · 0% payout

86.1%

Cat 1 · 0% payout

7.9%

Cat 2 · 50% payout

Cat 3 · 100% payout

1.9%

Cat 4 · 100% payout

0.8%

Cat 5 · 100% payout

0.1%

Category Mix: Historical vs. Simulated

Saffir-Simpson category, among years/storms that reached hurricane strength

■ Historical storms (peak intensity) ■ Simulated years (site wind)

Simulated bars skew lower — site wind is a storm's peak intensity after distance attenuation, so fewer years register the storm's full category.

Sample dataset is synthetic/hypothetical, built for methodology demonstration — not fitted to real NOAA HURDAT2 data. Upload your own workbook or CSV above to price against real data; the wind-speed column is auto-detected (override under the upload panel), and every KPI and chart recomputes from whatever is currently loaded.
